Telerik Academy

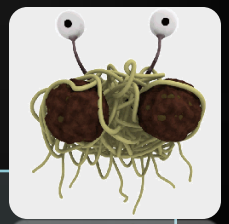
What Is String?

What Is String?

- Strings are sequences of characters
- Each character is a Unicode symbol
- Represented by the `string` data type in C# (`System.String`)
- Example:



```
string s = "Hello, C#";
```

The System.String Class

- Strings are represented by `System.String` objects in .NET Framework
  - String objects contain an immutable (read-only) sequence of characters
  - Strings use Unicode to support multiple languages and alphabets
- Strings are stored in the dynamic memory (managed heap)
- `System.String` is reference type

The System.String Class (2)

- String objects are like arrays of characters (char[])
  - Have fixed length (String.Length)
  - Elements can be accessed directly by index
    - The index is in the range [0...Length-1]

```
string s = "Hello!";
int len = s.Length; // len = 6
char ch = s[1]; // ch = 'e'
```

index =	0	1	2	3	4	5
s[index] =	H	e	l	l	o	!

Strings – First Example

```
static void Main()
{
    string s =
        "Stand up, stand up, Balkan Superman.";
    Console.WriteLine("s = \"{0}\"", s);
    Console.WriteLine("s.Length = {0}", s.Length);
    for (int i = 0; i < s.Length; i++)
    {
        Console.WriteLine("s[{0}] = {1}", i, s[i]);
    }
}
```

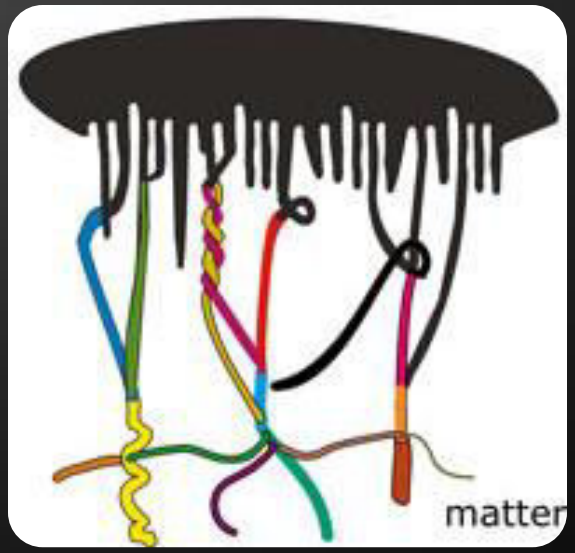
Strings – First Example

Live Demo

Telerik Academy

Creating and Using Strings

Declaring, Creating, Reading and Printing



Declaring Strings

- Several ways of declaring string variables:
  - Using the C# keyword `string`
  - Using the .NET's fully qualified class name `System.String`

```
string str1;
System.String str2;
String str3;
```

  - The above three declarations are equivalent

Creating Strings

- Before initializing a string variable has `null` value
- Strings can be initialized by:
  - Assigning a string literal to the string variable
  - Assigning the value of another string variable
  - Assigning the result of operation of type string

Creating Strings (2)

- Not initialized variables has value of `null`

```
string s; // s is equal to null
```

- Assigning a string literal

```
string s = "I am a string literal!";
```

- Assigning from another string variable

```
string s2 = s;
```

- Assigning from the result of string operation

```
string s = 42.ToString();
```

Reading and Printing Strings

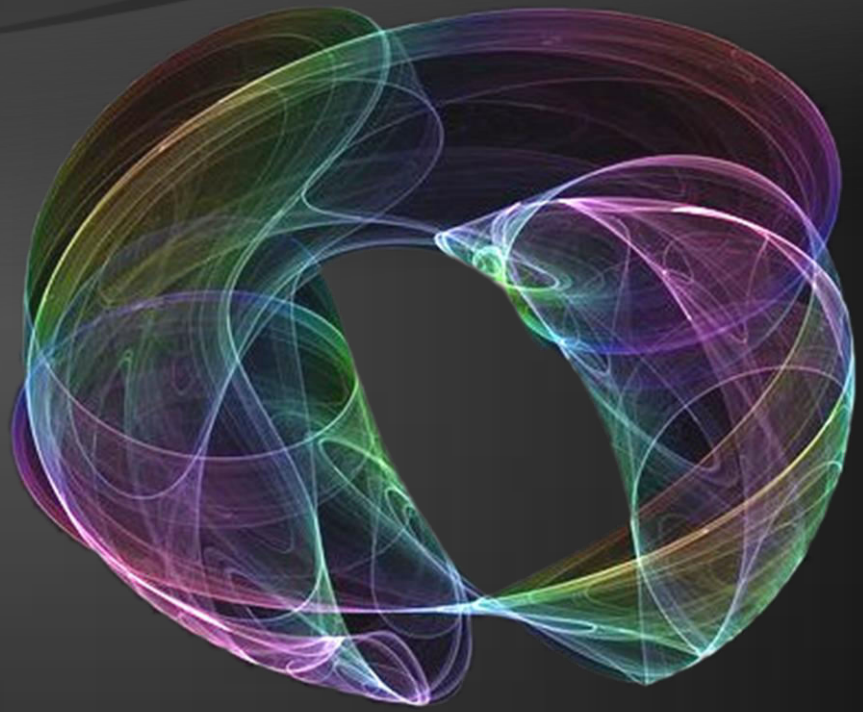
- Reading strings from the console
  - Use the method `Console.ReadLine()`

```
string s = Console.ReadLine();
```

- Printing strings to the console
  - Use the methods `Write()` and `WriteLine()`

```
Console.Write("Please enter your name: ");
string name = Console.ReadLine();
Console.Write("Hello, {0}! ", name);
Console.WriteLine("Welcome to our party!");
```

Telerik Academy



Reading and Printing Strings

Live Demo

Telerik Academy

Manipulating Strings

Comparing, Concatenating, Searching, Extracting Substrings, Splitting

Comparing Strings

- Several ways to compare two strings:
  - Dictionary-based string comparison
    - Case-insensitive

```
int result = string.Compare(str1, str2, true);
// result == 0 if str1 equals str2
// result < 0 if str1 is before str2
// result > 0 if str1 is after str2
```

    - Case-sensitive

```
string.Compare(str1, str2, false);
```

Comparing Strings (2)

- Equality checking by operator ==
  - Performs case-sensitive compare

```
if (str1 == str2)
{
    …
}
```

- Using the case-sensitive `Equals()` method
  - The same effect like the operator ==

```
if (str1.Equals(str2))
{
    …
}
```

Comparing Strings – Example

- Finding the first string in a lexicographical order from a given list of strings:

```
string[] towns = {"Sofia", "Varna", "Plovdiv",
   "Pleven", "Bourgas", "Rousse", "Yambol"};
string firstTown = towns[0];
for (int i=1; i<towns.Length; i++)
{
   string currentTown = towns[i];
   if (String.Compare(currentTown, firstTown) < 0)
   {
      firstTown = currentTown;
   }
}
Console.WriteLine("First town: {0}", firstTown);
```

Telerik Academy

Comparing Strings

Live Demo

Concatenating Strings

- There are two ways to combine strings:
  - Using the `Concat()` method

```
string str = String.Concat(str1, str2);
```

  - Using the + or the += operators

```
string str = str1 + str2 + str3;
string str += str1;
```

- Any object can be appended to a string

```
string name = "Peter";
int age = 22;
string s = name + " " + age; // → "Peter 22"
```

Concatenating Strings – Example

```
string firstName = "Svetlin";
string lastName = "Nakov";

string fullName = firstName + " " + lastName;
Console.WriteLine(fullName);
// Svetlin Nakov

int age = 25;

string nameAndAge =
    "Name: " + fullName +
    "\nAge: " + age;
Console.WriteLine(nameAndAge);
// Name: Svetlin Nakov
// Age: 25
```

Telerik Academy

Concatenating Strings

Live Demo

Searching in Strings

- Finding a character or substring within given string
  - First occurrence

```
IndexOf(string str)
```

  - First occurrence starting at given position

```
IndexOf(string str, int startIndex)
```

  - Last occurrence

```
LastIndexOf(string)
```

Telerik Academy

Searching in Strings – Example

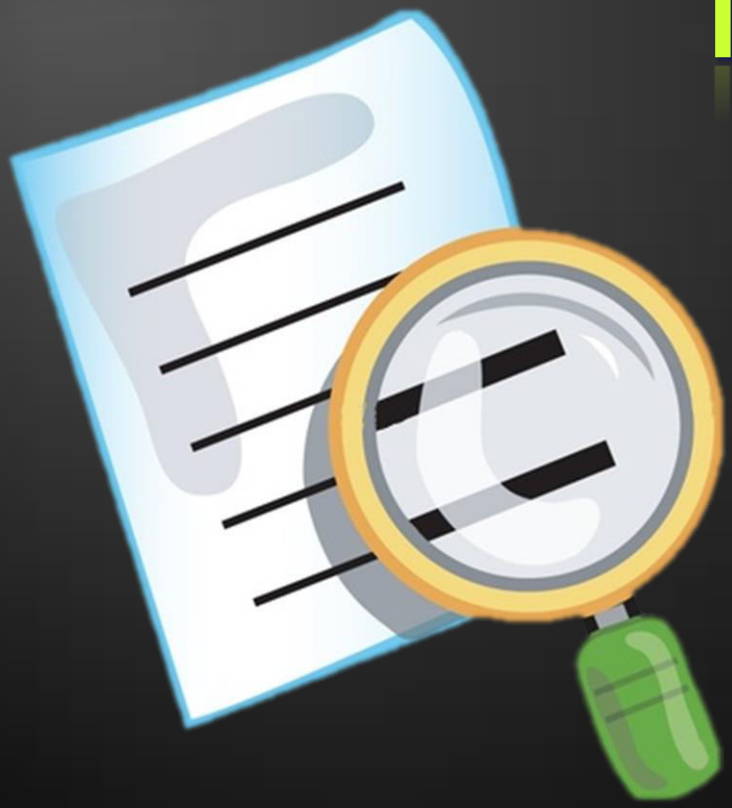
```
string str = "C# Programming Course";
int index = str.IndexOf("C#"); // index = 0
index = str.IndexOf("Course"); // index = 15
index = str.IndexOf("COURSE"); // index = -1
// IndexOf is case-sensetive. -1 means not found
index = str.IndexOf("ram"); // index = 7
index = str.IndexOf("r"); // index = 4
index = str.IndexOf("r", 5); // index = 7
index = str.IndexOf("r", 8); // index = 18
```

index =	0	1	2	3	4	5	6	7	8	9	10	11	12	13	…
s[index] =	C	#		P	r	o	g	r	a	m	m	i	n	g	…

Telerik Academy

Searching in Strings

Live Demo



Extracting Substrings

- Extracting substrings
  - `str.Substring(int startIndex, int length)`

```
string filename = @"C:\Pics\Rila2009.jpg";
string name = filename.Substring(8, 8);
// name is Rila2009
```

  - `str.Substring(int startIndex)`

```
string filename = @"C:\Pics\Summer2009.jpg";
string nameAndExtension = filename.Substring(8);
// nameAndExtension is Summer2009.jpg
```

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
C	:	\	P	i	c	s	\	R	i	l	a	2	0	0	5	.	j	p	g

Telerik Academy

Extracting Substrings

Live Demo

Splitting Strings

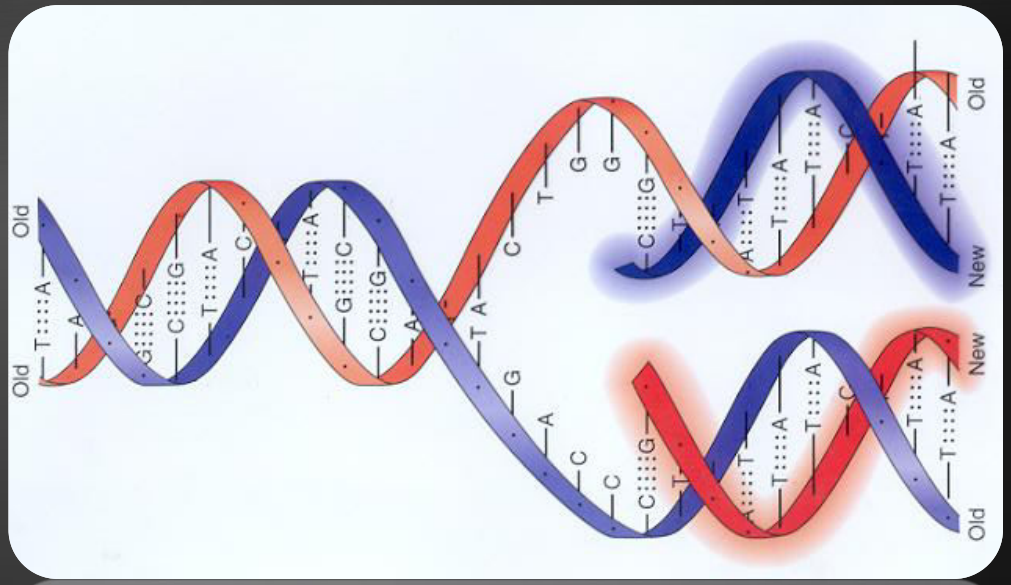
- To split a string by given separator(s) use the following method:

```
string[] Split(params char[])
```

- Example:

```
string listOfBeers =
    "Amstel, Zagorka, Tuborg, Becks.";
string[] beers =
    listOfBeers.Split(' ', ',', '.');
Console.WriteLine("Available beers are:");
foreach (string beer in beers)
{
    Console.WriteLine(beer);
}
```

Telerik Academy



Splitting Strings

Live Demo

Telerik Academy

Other String Operations

Replacing Substrings, Deleting Substrings, Changing Character Casing, Trimming

Telerik Academy

Replacing and Deleting Substrings

- `Replace(string, string)` – replaces all occurrences of given string with another
  - The result is new string (strings are immutable)

```
string cocktail = "Vodka + Martini + Cherry";
string replaced = cocktail.Replace("+", "and");
// Vodka and Martini and Cherry
```

- `Remove(index, length)` – deletes part of a string and produces new string as result

```
string price = "$ 1234567";
string lowPrice = price.Remove(2, 3);
// $ 4567
```

Changing Character Casing

- Using method ToLower()

```
string alpha = "aBcDeFg";
string lowerAlpha = alpha.ToLower(); // abcdefg
Console.WriteLine(lowerAlpha);
```

- Using method ToUpper()

```
string alpha = "aBcDeFg";
string upperAlpha = alpha.ToUpper(); // ABCDEFG
Console.WriteLine(upperAlpha);
```

Trimming White Space

- Using Trim()

```
string s = "    example of white space    ";
string clean = s.Trim();
Console.WriteLine(clean);
```

- Using Trim(chars)

```
string s = " \t\nHello!!! \n";
string clean = s.Trim(' ', ',' ,'!', '\n','\t');
Console.WriteLine(clean); // Hello
```

- Using TrimStart() and TrimEnd()

```
string s = "   C#   ";
string clean = s.TrimStart(); // clean = "C#   "
```

Telerik Academy

Other String Operations

Live Demo

Telerik Academy

Building and Modifying Strings

Using the StringBuilder Class

Constructing Strings

- Strings are immutable!
  - `Concat()`, `Replace()`, `Trim()`, … return new string, do not modify the old one
- Do not use "+" for strings in a loop!
  - It runs very, very inefficiently!

```
public static string DupChar(char ch, int count)
{
    string result = "";
    for (int i=0; i<count; i++)
        result += ch;
    return result;
}
```

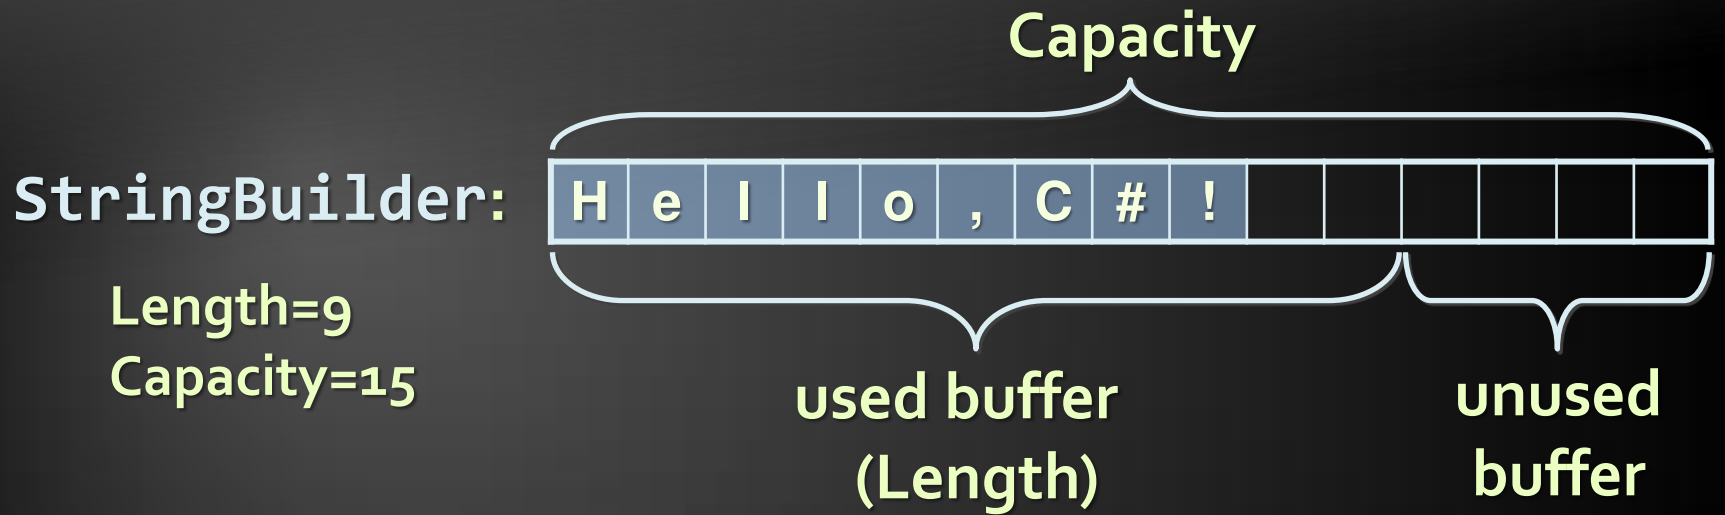
Very bad practice. Avoid this!

Telerik Academy

Slow Building Strings with +

Live Demo

StringBuilder: How It Works?



- `StringBuilder` keeps a buffer memory, allocated in advance
  - Most operations use the buffer memory and do not allocate new objects

Telerik Academy

How the + Operator Performs String Concatenations?

- Consider the following string concatenation:

```
string result = str1 + str2;
```

- It is equivalent to this code:

```
StringBuilder sb = new StringBuilder();
sb.Append(str1);
sb.Append(str2);
string result = sb.ToString();
```

- Several new objects are created and left to the garbage collector for deallocation
  - What happens when using + in a loop?

The StringBuilder Class

- `StringBuilder(int capacity)` constructor allocates in advance buffer of given size
  - By default 16 characters are allocated
- `Capacity` holds the currently allocated space (in characters)
- `this[int index]` (indexer in C#) gives access to the char value at given position
- `Length` holds the length of the string in the buffer

The StringBuilder Class (2)

- `Append(…)` appends a string or another object after the last character in the buffer
- `Remove(int startIndex, int length)` removes the characters in given range
- `Insert(int index, string str)` inserts given string (or object) at given position
- `Replace(string oldStr, string newStr)` replaces all occurrences of a substring
- `ToString()` converts the `StringBuilder` to `String`

Changing the Contents of a String with StringBuilder

- Use the `System.Text.StringBuilder` class for modifiable strings of characters:

```
public static string ReverseString(string s)
{
    StringBuilder sb = new StringBuilder();
    for (int i = s.Length-1; i >= 0; i--)
        sb.Append(s[i]);
    return sb.ToString();
}
```

- Use `StringBuilder` if you need to keep adding characters to a string

StringBuilder – Another Example

- Extracting all capital letters from a string

```
public static string ExtractCapitals(string s)
{
    StringBuilder result = new StringBuilder();
    for (int i = 0; i<s.Length; i++)
    {
        if (Char.IsUpper(s[i]))
        {
            result.Append(s[i]);
        }
    }
    return result.ToString();
}
```

Telerik Academy

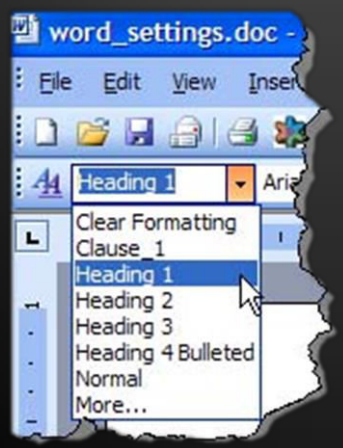
Using StringBuilder

Live Demo

Telerik Academy

Formatting Strings

Using `ToString()` and `String.Format()`



Method ToString()

- All classes in C# have public virtual method `ToString()`
  - Returns a human-readable, culture-sensitive string representing the object
  - Most .NET Framework types have own implementation of `ToString()`
    - `int`, `float`, `bool`, `DateTime`

```
int number = 5;
string s = "The number is " + number.ToString();
Console.WriteLine(s); // The number is 5
```

Telerik Academy

Method ToString(format)

- We can apply specific formatting when converting objects to string
  - ToString(formatString) method

```
int number = 42;
string s = number.ToString("D5"); // 00042

s = number.ToString("X"); // 2A

// Consider the default culture is Bulgarian
s = number.ToString("C"); // 42,00 лв

double d = 0.375;
s = d.ToString("P2"); // 37,50 %
```

Formatting Strings

- The formatting strings are different for the different types
- Some formatting strings for numbers:
  - D – number (for integer types)
  - C – currency (according to current culture)
  - E – number in exponential notation
  - P – percentage
  - X – hexadecimal number
  - F – fixed point (for real numbers)

Method String.Format()

- Applies templates for formatting strings
  - Placeholders are used for dynamic text
  - Like Console.WriteLine(…)

```
string template = "If I were {0}, I would {1}.";
string sentence1 = String.Format(
    template, "developer", "know C#");
Console.WriteLine(sentence1);
// If I were developer, I would know C#.

string sentence2 = String.Format(
    template, "elephant", "weigh 4500 kg");
Console.WriteLine(sentence2);
// If I were elephant, I would weigh 4500 kg.
```

Composite Formatting

- The placeholders in the composite formatting strings are specified as follows:

```
{index[,alignment][:formatString]}
```

- Examples:

```
double d = 0.375;
s = String.Format("{0,10:F5}", d);
// s = "   0,37500"

int number = 42;
Console.WriteLine("Dec {0:D} = Hex {1:X}",
    number, number);
// Dec 42 = Hex 2A
```

Formatting Dates

- Dates have their own formatting strings
  - d, dd – day (with/without leading zero)
  - M, MM – month
  - yy, yyyy – year (2 or 4 digits)
  - h, HH, m, mm, s, ss – hour, minute, second

```
DateTime now = DateTime.Now;
Console.WriteLine(
    "Now is {0:d.MM.yyyy HH:mm:ss}", now);
// Now is 31.11.2009 11:30:32
```

Cultures

- Cultures in .NET specify formatting / parsing settings specific to country / region / language
- Printing the current culture:

```
Console.WriteLine(System.Threading.
  Thread.CurrentThread.CurrentCulture);
```

- Changing the current culture:

```
System.Threading.Thread.CurrentThread.CurrentCulture =
  new CultureInfo("en-CA");
```

- Culture-sensitive `ToString()`:

```
CultureInfo culture = new CultureInfo("fr-CA");
string s = number.ToString("C", culture); // 42,00 $
```

Parsing Numbers and Dates

- Parsing numbers and dates is culture-sensitive
- Parsing a real number using "." as separator:

```
string str = "3.14";
Thread.CurrentThread.CurrentCulture =
  CultureInfo.InvariantCulture;
float f = float.Parse(str); // f = 3.14
```

- Parsing a date in specific format:

```
string dateStr = "25.07.2011";
DateTime date = DateTime.ParseExact(dateStr,
  "dd.MM.yyyy", CultureInfo.InvariantCulture);
```

Telerik Academy

Formatting Strings

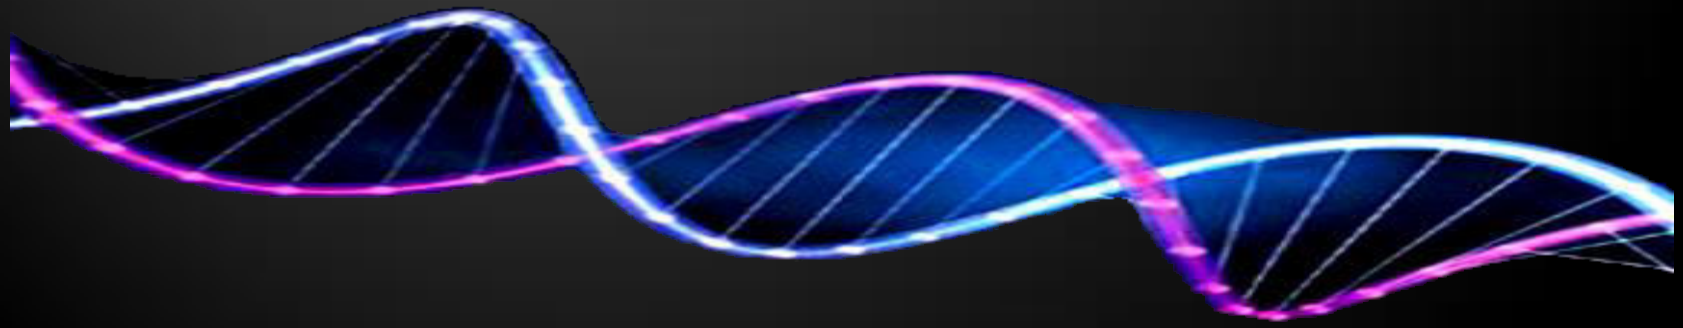
Live Demo

Summary

- Strings are immutable sequences of characters (instances of `System.String`)
  - Declared by the keyword string in C#
  - Can be initialized by string literals
- Most important string processing members are:
  - `Length`, `this[]`, `Compare(str1, str2)`, `IndexOf(str)`, `LastIndexOf(str)`, `Substring(startIndex, length)`, `Replace(oldStr, newStr)`, `Remove(startIndex, length)`, `ToLower()`, `ToUpper()`, `Trim()`

Summary (2)

- Objects can be converted to strings and can be formatted in different styles (using `ToString()` method)
- Strings can be constructed by using placeholders and formatting strings (`String.Format(…)`)



Telerik Academy

Strings and Text Processing

Questions?

http://csharpfundamentals.telerik.com

Exercises

1. Describe the strings in C#. What is typical for the `string` data type? Describe the most important methods of the `String` class.
2. Write a program that reads a string, reverses it and prints the result at the console.

   Example: "sample" → "elpmas".
3. Write a program to check if in a given expression the brackets are put correctly.

   Example of correct expression: `((a+b)/5-d)`.

   Example of incorrect expression: `)(a+b))`.

Exercises (2)

4. Write a program that finds how many times a substring is contained in a given text (perform case insensitive search).

   Example: The target substring is "`in`". The text is as follows:

```
We are living in an yellow submarine. We don't
have anything else. Inside the submarine is very
tight. So we are drinking all the day. We will
move out of it in 5 days.
```

   The result is: 9.

Exercises (3)

5. You are given a text. Write a program that changes the text in all regions surrounded by the tags <upcase> and </upcase> to uppercase. The tags cannot be nested. Example:

```
We are living in a <upcase>yellow
submarine</upcase>. We don't have
<upcase>anything</upcase> else.
```

The expected result:

```
We are living in a YELLOW SUBMARINE. We don't have
ANYTHING else.
```

Exercises (4)

6. Write a program that reads from the console a string of maximum 20 characters. If the length of the string is less than 20, the rest of the characters should be filled with '*'. Print the result string into the console.
7. Write a program that encodes and decodes a string using given encryption key (cipher). The key consists of a sequence of characters. The encoding/decoding is done by performing XOR (exclusive or) operation over the first letter of the string with the first of the key, the second – with the second, etc. When the last key character is reached, the next is the first.

Exercises (5)

8. Write a program that extracts from a given text all sentences containing given word.

   Example: The word is "in". The text is:

```
We are living in a yellow submarine. We don't have
anything else. Inside the submarine is very tight.
So we are drinking all the day. We will move out
of it in 5 days.
```

   The expected result is:

```
We are living in a yellow submarine.
We will move out of it in 5 days.
```

   Consider that the sentences are separated by "." and the words – by non-letter symbols.

Exercises (6)

9. We are given a string containing a list of forbidden words and a text containing some of these words. Write a program that replaces the forbidden words with asterisks. Example:

```
Microsoft announced its next generation PHP
compiler today. It is based on .NET Framework 4.0
and is implemented as a dynamic language in CLR.
```

Words: "PHP, CLR, Microsoft"

The expected result:

```
********* announced its next generation ***
compiler today. It is based on .NET Framework 4.0
and is implemented as a dynamic language in ***.
```

Exercises (7)

10. Write a program that converts a string to a sequence of C# Unicode character literals. Use format strings. Sample input:

```
Hi!
```

Expected output:

```
\u0048\u0069\u0021
```

11. Write a program that reads a number and prints it as a decimal number, hexadecimal number, percentage and in scientific notation. Format the output aligned right in 15 symbols.

Exercises (8)

12. Write a program that parses an URL address given in the format:

```
[protocol]://[server]/[resource]
```

and extracts from it the [protocol], [server] and [resource] elements. For example from the URL http://www.devbg.org/forum/index.php the following information should be extracted:

```
[protocol] = "http"
[server] = "www.devbg.org"
[resource] = "/forum/index.php"
```

Exercises (9)

13. Write a program that reverses the words in given sentence.

    Example: "C# is not C++, not PHP and not Delphi!" → "Delphi not and PHP, not C++ not is C#!".

14. A dictionary is stored as a sequence of text lines containing words and their explanations. Write a program that enters a word and translates it by using the dictionary. Sample dictionary:

```
.NET – platform for applications from Microsoft
CLR – managed execution environment for .NET
namespace – hierarchical organization of classes
```

Exercises (10)

15. Write a program that replaces in a HTML document given as string all the tags … with corresponding tags [URL=…]…/URL]. Sample HTML fragment:

```
<p>Please visit <a href="http://academy.telerik.
com">our site</a> to choose a training course. Also
visit <a href="www.devbg.org">our forum</a> to
discuss the courses.</p>
```

↓

```
<p>Please visit [URL=http://academy.telerik.
com]our site[/URL] to choose a training course.
Also visit [URL=www.devbg.org]our forum[/URL] to
discuss the courses.</p>
```

Exercises (11)

16. Write a program that reads two dates in the format: `day.month.year` and calculates the number of days between them. Example:

```
Enter the first date: 27.02.2006
Enter the second date: 3.03.2006
Distance: 4 days
```

17. Write a program that reads a date and time given in the format: `day.month.year hour:minute:second` and prints the date and time after 6 hours and 30 minutes (in the same format) along with the day of week in Bulgarian.

Exercises (12)

18. Write a program for extracting all email addresses from given text. All substrings that match the format `<identifier>@<host>…<domain>` should be recognized as emails.
19. Write a program that extracts from a given text all dates that match the format `DD.MM.YYYY`. Display them in the standard date format for Canada.
20. Write a program that extracts from a given text all palindromes, e.g. `"ABBA"`, `"lamal"`, `"exe"`.

Exercises (13)

21. Write a program that reads a string from the console and prints all different letters in the string along with information how many times each letter is found.
22. Write a program that reads a string from the console and lists all different words in the string along with information how many times each word is found.
23. Write a program that reads a string from the console and replaces all series of consecutive identical letters with a single one. Example: "aaaaabbbbbcdddeeeeedssaa" → "abcdedsa".

Exercises (14)

24. Write a program that reads a list of words, separated by spaces and prints the list in an alphabetical order.
25. Write a program that extracts from given HTML file its title (if available), and its body text without the HTML tags. Example:

```
<html>
  <head><title>News</title></head>
  <body><p><a href="http://academy.telerik.com">Telerik
    Academy</a>aims to provide free real-world practical
    training for young people who want to turn into
    skillful .NET software engineers.</p></body>
</html>
```
